

# ACT Sheet

## Newborn Screening ACT Sheet [Hemoglobin FE] Hemoglobin E/E or Hemoglobin E/Beta Zero Thalassemia (Hb E/E or Hb E/β<sup>0</sup> Thalassemia)

**Differential Diagnosis:** Homozygous Hemoglobin E; Hemoglobin E/Beta Zero ( $\beta^0$ ) Thalassemia; Hemoglobin E/Beta Plus ( $\beta^+$ ) Thalassemia.

**Condition Description:** Hemoglobin E/E or Hemoglobin E/ $\beta^0$  Thalassemia are inherited types of red blood cell disorders characterized by abnormal hemoglobin production. They are due to genetic changes in the beta hemoglobin chain. Although Hb E/E is generally benign, HbE/ $\beta^0$  Thalassemia has a variable clinical course ranging from moderate anemia to transfusion dependency.

#### You Should Take the Following Actions:

- Inform family of the newborn screening result.
- Ascertain clinical status (newborns are expected to be asymptomatic).
- Evaluate the newborn (newborns are expected to be asymptomatic and have a normal clinical exam. If significant signs or symptoms are identified, it is likely related to a different underlying disorder).
- Consult with pediatric hematologist with expertise in hemoglobin disorders within the first week of life with follow up typically recommended between 2-4 months age (it is unusual to have symptoms before 2-4 months of life).
- Coordinate confirmatory diagnostic testing and management as recommended by specialist.
- Provide family with basic information about Hemoglobin E/E or Hemoglobin E/Beta Zero ( $\beta^0$ ) Thalassemia.
- Refer for genetic counseling.
- Report final diagnostic outcome to newborn screening program.

**Diagnostic Evaluation:** The hemoglobins are listed in order of the amount of hemoglobin present on the newborn screen (F>E). <u>Hemoglobin electrophoresis, isoelectric focusing, or high performance liquid chromatography</u> (<u>HPLC</u>): is used to confirm the newborn screening result. <u>Complete blood count (with focus on hemoglobin, mean corpuscular volume, smear, and reticulocyte count)</u>: may be normal at birth but may demonstrate a microcytic anemia as early as two months of life. <u>Molecular genetic testing</u>: is required to confirm the diagnosis and to distinguish homozygous Hb E/E from Hb E/β<sup>0</sup> Thalassemia.

**Clinical Considerations:** While hemoglobin E/E is clinically benign, Hb  $E/\beta^0$  Thalassemia has a variable presentation. Most individuals with Hb  $E/\beta^0$  Thalassemia have moderately severe anemia, hepatosplenomegaly, intermittent jaundice, growth restriction, and overexpansion of the bone marrow. Severely affected individuals require life-long transfusion, possible splenectomy, and treatment for iron overload. Monitoring will vary depending on the specific diagnosis and should be done under the direction of a pediatric hematologist. Iron supplements should be avoided unless iron deficiency is documented.
