## Newborn Screening ACT Sheet [Elevated Methionine +/- Elevated Homocysteine] Homocystinuria (Cystathionine beta-synthase deficiency [CBS Deficiency])

**Differential Diagnosis:** Classic homocystinuria, methionine adenosyltransferase (MAT) I/III deficiency, glycine n-methyltransferase (GNMT) deficiency; adenosylhomocysteine hydrolase deficiency, liver disease, parenteral nutrition, prematurity.

**Condition Description:** Homocystinuria refers to a group of inherited disorders that result in elevated levels of homocysteine. The amino acid, methionine, derived from ingested protein, is normally converted to homocysteine. In classic homocystinuria, homocysteine cannot be converted to cystathionine. As a result, the concentration of homocysteine and its precursor, methionine, become elevated. In MAT I/III deficiency and the other hypermethioninemias, methionine is increased but homocysteine levels are normal or only slightly increased. Presentation in the neonatal period is rare.

### You Should Take the Following Actions:

- Inform family of the newborn screening result.
- Ascertain clinical status (newborns are expected to be asymptomatic).
- Consult with pediatric metabolic specialist.
- Evaluate the newborn with attention to liver disease.
- Initiate confirmatory/diagnostic testing and management, as recommended by the specialist.
- Provide family with basic information about the possible diagnoses and their management.
- Report the final diagnostic outcome to newborn screening program.

**Diagnostic Evaluation:** Plasma amino acids: Methionine is elevated in both classic homocystinuria (cystathionine-b-synthase deficiency) and in the other disorders. Total plasma homocysteine is markedly elevated in classic homocystinuria and normal or only slightly increased in the other disorders. Molecular genetic testing may be required to establish the diagnosis.

**Clinical Considerations:** Neonates with classic homocystinuria are usually asymptomatic. Treatment includes a protein restricted diet and vitamin supplementation. If untreated, later features may include ectopia lentis, developmental delay, abnormalities in long bone formation and an increased risk of thrombosis. MAT I/III deficiency may be benign. Adenosylhomocysteine hydrolase deficiency is a very rare condition associated with developmental delay and hypotonia, and both this disorder and GNMT deficiency can cause liver abnormalities.

This ACT sheet and algorithm is designed primarily as an educational resource for medical geneticists and other clinicians to help them provide quality medical services. Adherence to this practice resource is completely voluntary and does not necessarily assure a successful medical outcome. This ACT sheet and algorithm should not be considered inclusive of all proper procedures and tests or exclusive of other procedures and tests that are reasonably directed to obtaining the same results. In determining the propriety of any specific procedure or test, the clinician should apply his or her own professional judgment to the specific clinical circumstances presented by the individual patient or specimen. Clinicians are encouraged to document the reasons for the use of a particular procedure or test, whether or not it is in conformance with this ACT sheet and algorithm. Clinicians also are advised to take notice of the date this ACT sheet and algorithm was adopted, and to consider other medical and scientific information that becomes available after that date. It also would be prudent to consider whether intellectual property interests may restrict the performance of certain tests and other procedures. Where individual authors are listed, the views expressed may not reflect those of the authors' employers or affiliated institutions.
