Citrin Deficiency  
(Citrullinemia II)  
[Urea Cycle Disorder]

Condition Description: Citrin deficiency is an autosomal recessive genetic disorder. It is a secondary disorder of the urea cycle (whereby ammonia is converted to urea). Citrin is a transporter that delivers aspartate to the urea cycle enzyme. A defect in this transporter results in secondary reduction of argininosuccinate synthetase, a urea cycle enzyme. Elevated citrulline in the blood is a key finding.

Clinical Considerations: Citrin deficiency in adults is characterized by recurrent episodes of hyperammonemia. Affected individuals may have had hepatic disease in infancy. Excessive protein intake in relation to their diet and/or catabolism due to stress (prolonged fasting, infection, fever, pregnancy and postpartum, surgery, systemic steroids) can lead to hyperammonemia. Valproic acid should be avoided. Immediate clinical evaluation is required when the patient exhibits fever or signs and symptoms of hyperammonemia, such as sleepiness, recurrent vomiting, neurologic and psychiatric findings. Pancreatitis, hyperlipidemia, fatty liver and hepatoma may occur. Pregnancies should be considered high risk. There are generally no special considerations with puberty, sexual function and fertility.

THE TRANSITION TEAM SHOULD TAKE THE FOLLOWING ACTIONS:
- Initiate a dialogue among transition team members and establish an adult medical home.
- Facilitate consistency and coordination of care among multiple health care providers as the patient transitions to independent living (to include college, relocation, employment).
- Consult with specialists (ideally the metabolic specialist and dietitian caring for the patient) to establish a co-management plan, including input from the patient/family. This care plan should include:
  - Nutritional assessment (diet low in carbohydrates and high in protein)
  - Up to date immunizations
  - Avoidance of valproic acid and systemic steroids
- Confirm the diagnosis by review of the medical record and previous laboratory studies.
- Order laboratory studies as indicated (blood ammonia and plasma amino acids).
- Identify the patient's health care coverage (including insurance) and access to care.
- Assess and address the patient's psychological, behavioral, and social service needs.
- Offer health education and genetic counseling concerning future reproductive decisions.
- Make patient aware of urea cycle disorders support group.

Disclaimer: This guideline is designed primarily as an educational resource for clinicians to help them provide quality medical care. It should not be considered inclusive of all proper procedures and tests or exclusive of other procedures and tests that are reasonably directed to obtaining the same results. Adherence to this guideline does not necessarily ensure a successful medical outcome. In determining the propriety of any specific procedure or test, the clinician should apply his or her own professional judgment to the specific clinical circumstances presented by the individual patient or specimen. Clinicians are encouraged to document the reasons for the use of a particular procedure or test, whether or not it is in conformance with this guideline. Clinicians also are advised to take notice of the date this guideline was adopted, and to consider other medical and scientific information that become available after that date.
